Research Ethics & Compliance Support

Guidelines for Monitoring and Management of Rectal Prolapse in Mice

**Purpose:** This guideline has been developed to ensure the wellbeing of mice exhibiting signs of rectal prolapse and to reduce premature killing of experimental animals due to this condition.

**Background:**

Rectal prolapse is a commonly encountered condition in laboratory mice. The condition may occur spontaneously, related to specific genetic manipulations or specific experimental models as well be linked to parasitic, viral or bacterial infections.²,⁴,⁶ Mice are particularly susceptible to rectal prolapse because they have a very short rectum where the descending colon, enveloped in serosa, extends almost to the anus.³ Therefore, a rectal prolapse in mice can occur simply because of straining during parturition or defaecation.

**Symptoms:**

Rectal prolapse can be defined as the eversion of the rectal mucosa beyond the rectal opening³, presenting as a small red mass at the anus. As a consequence, the prolapsed rectal tissue may bleed or become dry and necrotic. Presence of blood staining/marking on bedding, cage walls or environmental enrichment may be indicative of a mouse with this condition.

**Assessment:**

The degree of severity is assessed based on measurement of the prolapsed rectal tissue and the clinical condition of the mouse.

Measuring the prolapsed tissue:

A. **Diameter of the rectal prolapse:** measure the diameter of the rectal prolapse when viewed from the front. (Photo: UNSW, 2017³)

B. **Protrusion of the rectal tissue:** measure the distance the tissue is extending out of the anus as viewed from the side. (Photo: Manesh Kumar, 2004)
### Mild Rectal Prolapse
- **Animal:** Bright, alert, and responsive
- **Prolapse tissue size:** Diameter: <3 mm; Protrusion: <1 mm
- **Prolapsed tissue condition:** Moist, pink

### Moderate Rectal Prolapse
- **Animal:** Bright, alert, and responsive
- **Prolapse tissue size:** Diameter: 3 – 7 mm; Protrusion: 2 – 4 mm
- **Tissue condition:** Moist, pink, no active bleeding

### Severe Rectal Prolapse
- **Animal:** Quiet, alert, and responsive and exhibits one or more of the following clinical signs:
- **Prolapse tissue size:** Diameter: > 7 mm; Protrusion: > 4 mm
- **Tissue condition:** Ulcerated, dry, dark red to black, active bleeding/dry blood

---

#### Decision Tree for Rectal Prolapse Management

**RECTAL PROLAPSE IN MICE**

- **Mild Rectal Prolapse**
  - Animal: Bright, alert and responsive
  - Prolapse tissue size: Diameter: <3 mm; Protrusion: <1 mm
  - Prolapsed tissue condition: Moist, pink

- **Moderate Rectal Prolapse**
  - Animal: Bright, alert and responsive
  - Prolapse tissue size: Diameter: 3 – 7 mm; Protrusion: 2 – 4 mm
  - Tissue condition: Moist, pink, no active bleeding

- **Severe Rectal Prolapse**
  - Animal: Quiet, alert and responsive and exhibits one or more of the following clinical signs:
  - Prolapse tissue size: Diameter: > 7 mm; Protrusion: > 4 mm
  - Tissue condition: Ulcerated, dry, dark red to black, active bleeding/dry blood

**Is treatment an option?**

- **Yes**
  - **Treatment**
    - Flush/clean prolapsed tissue with saline, apply protective ointment
    - Where possible, give wet feed or gel food and consider including soft bedding
    - Review treatment management:
      - Has the condition progressed in severity?
        - **No**
          - Treatment: Continue as above
        - **Yes**
          - Consult University Veterinarian

- **No**
  - **Euthanasia**
    - Recommend euthanasia based on euthanasia criteria
    - For valuable, irreplaceable or pregnant animals must consult veterinarian immediately

---

Treatment and Monitoring:

- It is the investigator’s responsibility to determine any potential impact of this condition and proposed treatment on their experimental outcome.
- Although a surgical procedure for reducing rectal prolapse has been described, surgery on small prolapses likely causes more damage to the mucosa than treating the site conservatively.
- Treatment for mild and moderate prolapses should focus on minimising damage to the prolapsed tissue through the following:
  1) Flush area with sterile saline to remove any debris
  2) Apply a thin layer of protective cream/ointment (e.g. Bepanthen™, Sudocream™, Vaseline™, antibiotic ointment etc.) as determined by the University Veterinarians
  3) Where possible, give moistened feed or commercially available gel food
  4) Where possible, consider including soft bedding e.g. Protowels™, tissue paper to reduce irritation and potential damage to prolapsed tissue
- It is recommended that mice are treated at least once daily (including weekends), preferably 2-3 times per day as needed and assessed each day to ensure that their condition is not worsening.
- Where possible, provision should be that animals suffering from rectal prolapse, should be allocated to the shortest experimental time-point.
- Animals are to be re-evaluated by veterinarians during the treatment period.

Euthanasia criteria:

Immediate euthanasia is required for mice with rectal prolapse that meet one or more of the following criteria:

- Severe rectal prolapse and/or
- Prolapsed tissues is ulcerated with excessive bleeding, desiccated or necrotic (dark red to black)
- The animal is showing any of the clinical signs pain or distress including loss of normal behaviour, reduced activity, ruffled fur, hunched posture, dehydration, weight loss equal to or greater than 20%, clinical signs of

Contact the University Veterinarians if assistance is required for critical assessment of mice with rectal prolapse.

Comments

An increased incidence of rectal prolapses in a colony may be a symptom of underlying conditions such as enteric diseases, underlying parasitic, viral or bacterial infections or linked to a specific phenotype. This should be reported to the animal facility and the University Veterinary Staff for further investigation and management.

Female breeding mice exhibiting clinical signs of rectal prolapses should not be bred, unless approved by University Veterinarians.
